

Most Useful SPICELIB Subroutines

NAIF
March 1999

This document contains a brief description of the most often used SPICELIB routines. These are routines for reading different kinds of navigation and ancillary information and solving tasks of 3-dimensional geometry.

In this document routines are grouped by category. A list of these categories and actions performed by the particular routines is in the first chapter.

For each routine in this document you will find the following information:

1. short description of action performed by routine;
2. routine calling sequence;
3. declaration of routine's arguments.

Full information for each particular routine can be found in the header section of routine's source code.

Measurement units for arguments of SPICELIB routines described here are kilometers for distances and radians for angles.

<i>Solar system bodies and spacecrafts ID codes.</i>	<i>page 7</i>
<ul style="list-style-type: none">• list of SPICE ID codes for solar system bodies and spacecrafts.	
<i>Inertial reference frames.</i>	<i>page 8</i>
<ul style="list-style-type: none">• list of codes and names for inertial reference frames;• list of names for body-fixed rotation frame;• other frames used with SPICE system.	
<i>Universal and ephemeris times.</i>	<i>page 9</i>
<ul style="list-style-type: none">• loading of LSK file containing ET–UTC mapping data;• calculation of ephemeris time ET from universal time UTC;• calculation of universal time UTC from ephemeris time ET.	
<i>Spacecraft on-board time (SCLK).</i>	<i>page 10</i>
<ul style="list-style-type: none">• loading of SCLK file containing ET–SCLK mapping data;• transformation of SCLK given as character string to its double precision encoding;• transformation of encoded double precision SCLK to corresponding character string;• calculation of encoded SCLK for given ephemeris time ET;• calculation of ephemeris time ET for SCLK given as its double precision encoding;• calculation of character string SCLK for given ephemeris time ET;• calculation of ephemeris time for SCLK given as character string.	
<i>Constants and matrixes of planets and satellites (PCK).</i>	<i>page 11</i>
<ul style="list-style-type: none">• loading of PCK file containing physical constants for planet and satellites;• calculation of transformation matrix from inertial to body-fixed reference frame;• calculation of transformation matrix from inertial “J2000” to body-fixed reference frame;• calculation of Euler angles defining transformation from inertial “J2000” to body-fixed reference frame;• retrieval of values of body’s physical parameter from previously loaded data.	
<i>Frame transformations (FRAMES).</i>	<i>page 12</i>
<ul style="list-style-type: none">• loading of FRAMES kernel file containing project specific frame definitions;• calculation of state transformation matrix, rotating state vectors (position and velocity) from one frame to another;• naming convention for PCK-based frames;• naming convention for user-defined (CK-based and fixed offset) frames;	
<i>Planet and spacecraft positions (SPK).</i>	<i>page 13</i>
<ul style="list-style-type: none">• loading of SPK file containing Solar system bodies and spacecrafts trajectory data;• calculation of apparent, true or geometric state (position and velocity) of one body (planet, satellite, spacecraft, ...) in respect to another body for given ephemeris time ET;• calculation of geometric state of one body in respect to another body for given ET;• unloading of previously loaded SPK files.	
<i>Attitude of spacecrafts and instrument platforms (CK).</i>	<i>page 14</i>
<ul style="list-style-type: none">• loading of CK file containing spacecraft’s and instrument platform’s attitude data;• calculation of attitude matrix (rotating vectors from given inertial to spacecraft- or platform-fixed reference frame) for time given as encoded SCLK;• calculation of attitude matrix and angular velocity of rotation of spacecraft- or platform-fixed reference frame relate to given inertial frame for given encoded SCLK;• unloading of previously loaded CK file.	
<i>Scientific instruments parameters (IK).</i>	<i>page 15</i>
<ul style="list-style-type: none">• loading of IK file containing data describing particular scientific instrument;• retrieval of values of instrument’s physical parameter from previously loaded data.	
<i>Star Catalog.</i>	<i>page 16</i>
<ul style="list-style-type: none">• loading of SPICE Star Catalog file containing star position at particular epoch;• searching for stars within specified RA–DEC box;• getting catalog number, position data, spectral type and visual magnitude for each star found during previous search;	

Spacecraft Event Information (Data Base Kernel).**page 17**

- loading of SPICE EK (DBK) file containing spacecraft event data;
- searching EK data satisfying a set of constraints specified in a query string;
- returning integer, double precision or character elements of an EK data record found during previous search;

Physical and mathematical constants.**page 19**

- values of π , $\pi/2$ and 2π ;
- numbers of degrees per radian and radians per degree;
- number of seconds per day;
- IAU official value of light speed in vacuum;
- values of Julian date for B1900, B1950, J1900, J1950, J2000 and J2100.

3-dimensional geometry

Rectangular coordinates.**page 20**

- cylindrical coordinates of a point from its rectangular coordinates;
- geodetic coordinates of a point from its rectangular coordinates;
- latitudinal coordinates of a point from its rectangular coordinates;
- right ascension, declination and distance to origin of a point from its rectangular coordinates;
- spherical coordinates of a point from its rectangular coordinates.

Spherical and cylindrical coordinates.**page 21**

- latitudinal coordinates of a point from its cylindrical coordinates;
- rectangular coordinates of a point from its cylindrical coordinates;
- spherical coordinates of a point from its cylindrical coordinates;
- cylindrical coordinates of a point from its spherical coordinates;
- latitudinal coordinates of a point from its spherical coordinates;
- rectangular coordinates of a point from its spherical coordinates.

Latitudinal and geodetic coordinates.**page 22**

- cylindrical coordinates of a point from its latitudinal coordinates;
- rectangular coordinates of a point from its latitudinal coordinates;
- spherical coordinates of a point from its latitudinal coordinates;
- rectangular coordinates of a point from its geodetic coordinates;
- rectangular coordinates of a point on the surface of body from its geodetic latitude and longitude;
- rectangular coordinates of a point from its right ascension, declination and distance to origin.

Simple operations on vectors.**page 23**

- addition of two vectors;
- subtraction of two vectors;
- cross product of two vectors;
- dot product of two vectors;
- product of vector and scalar;
- negation of given vector;
- coping of given vector;
- indication either given vector is zero vector;
- angular separation between two vectors;
- distance between two vectors;
- magnitude of vector;
- unit vector along with given vector;
- unit vector along with cross product of two vectors;
- magnitude and unit vector along with given vector.

Projections, linear combinations and rotation of vectors.

page 24

- vector's component rectangular to other vector;
- projection of vector into other vector;
- rotation of vector by given angle about axis given by other vector;
- rotation of vector by given angle about one of reference axis (X, Y or Z);
- point on the given line and nearest to given point;
- orthogonal projection of vector onto given plane;
- vector projection onto plane inverted;
- linear combination of two vectors;
- linear combination of three vectors.

Operations on matrixes.

page 25

- product of two matrixes;
- product of matrix and the transpose of other matrix;
- product of matrix and vector;
- product of the transpose of matrix and other matrix;
- product of the transpose of matrix and vector;
- product of the transpose of vector, matrix and other vector;
- transpose of given matrix;
- coping of given matrix;
- determinant of given matrix;
- trace of given matrix.

Operations on planes.

page 26

- plane from normal vector and distance from origin;
- plane from point and normal vector;
- plane from point and two vectors;
- normal vector and distance from origin for given plane;
- point and normal vector for given plane;
- point and two vectors for given plane;
- intersection of ray and plane.

Operations on ellipses.

page 27

- ellipse from center and two generating vectors;
- center and axis for given ellipse;
- axis of ellipse from two generating vectors;
- intersection of ellipse and plane;
- point on given ellipse and nearest to given point;
- projection of ellipse onto plane.

Operations on ellipsoids.

page 28

- point on given ellipsoid and nearest to given point;
- intersection of ray and ellipsoid;
- normal vector for given point on ellipsoid surface;
- limb on ellipsoid surface;
- point on given ellipsoid and nearest to given line;
- intersection of ellipsoid and plane.

Creation of transformation matrixes.

page 29

- calculation of matrix rotating vector about specified reference axis (X, Y or Z);
- rotation of given matrix about specified reference axis (X, Y or Z);
- calculation of matrix rotating vectors to reference frame, principal axis of which are specified by two given vectors;
- indication either given matrix is rotation matrix;
- calculation of matrix from given Euler angles;
- calculation of Euler angles for given matrix.

Orbital elements.

page 30

- calculation of spacecraft position and velocity for given time and set of orbital elements;
- calculation of orbital elements for given position and velocity of spacecraft and gravitational parameter of planet.

Solar system bodies and spacecrafts ID codes.

Planet Barycenters

Positive ID from 0 to 10 are assigned to Solar system planets barycenters, Solar system barycenter and Sun.

0	Solar system barycenter
1	Mercury barycenter
2	Venus barycenter
3	Earth barycenter
4	Mars barycenter
5	Jupiter barycenter
6	Saturn barycenter
7	Uranus barycenter
8	Neptune barycenter
9	Pluto barycenter
10	Sun

Planet Mass Centers

The code for each planet is computed by adding 99 to the code of the planet's barycenter multiplied by 100.

199	Mercury (equivalent to 1)
299	Venus (equivalent to 2)
399	Earth
499	Mars (equivalent to 4)
599	Jupiter
699	Saturn
799	Uranus
899	Neptune
999	Pluto

Satellites

The code for a satellite is computed by adding its IAU designation to the code of its planet barycenter multiplied by 100.

301	Moon
-----	------

401	Phobos
402	Deimos

501	Io
502	Europe
503	Ganymede
etc.	etc.

Spacecrafts, on-board scientific instruments

Negative codes are used for spacecrafts. So, S/C “MGS” has ID **-94**, “Mars Polar Lander” — **-116**, “Mars Climate Orbiter” — **-127**, “Galileo orbiter” — **-77**, “Stardust” — **-29**, “Cassini” — **-82**, etc. The ID for a particular spacecraft is assigned by NAIF/JPL. These are often based on NASA DSN designations. See the document *NAIF IDs Required Reading* for a complete list.

The code of on-board scientific instrument or instrument platform is normally computed by adding its ID code assigned by project staff to the code of the spacecraft multiplied by 1000. For example, the code of the first instrument platform of the spacecraft with ID **-23** would be **-23001**.

Inertial Reference Frames

Codes and names of standard inertial reference frames.

The names and integer codes of standard inertial reference frames supported by the SPICE toolkit are given in the table below. They are used as arguments in some SPICELIB routines.

Code	Name	Description
1	J2000	Earth mean equator, dynamical equinox of J2000
2	B1950	Earth mean equator, dynamical equinox of B1950
3	FK4	Fundamental Catalog (4)
4	DE-118	JPL Developmental Ephemeris (118)
5	DE-96	JPL Developmental Ephemeris (96)
6	DE-102	JPL Developmental Ephemeris (102)
7	DE-108	JPL Developmental Ephemeris (108)
8	DE-111	JPL Developmental Ephemeris (111)
9	DE-114	JPL Developmental Ephemeris (114)
10	DE-122	JPL Developmental Ephemeris (122)
11	DE-125	JPL Developmental Ephemeris (125)
12	DE-130	JPL Developmental Ephemeris (130)
13	GALACTIC	Galactic System II
14	DE-200	JPL Developmental Ephemeris (200)
15	DE-202	JPL Developmental Ephemeris (202)
16	MARSIAU	Mars Mean Equator and IAU vector of J2000
17	ECLIPJ2000	Ecliptic coordinates based upon the J2000 frame
18	ECLIPB1950	Ecliptic coordinates based upon the B1950 frame
19	DE-140	JPL Developmental Ephemeris (140)
20	DE-142	JPL Developmental Ephemeris (142)
21	DE-143	JPL Developmental Ephemeris (143)
22	DE-145	JPL Developmental Ephemeris (145)

All **DE-2XX** and **DE-4XX** frames are, by definition, **J2000** frames. So unique identifiers for these are not needed.

Names of body-fixed rotating frames.

Body-fixed rotating frames for all Solar System bodies are defined within the SPICE system. The name of such a frame for a particular body is constructed by adding the prefix "**IAU_**" to the body name. For example, the name of the Mars body-fixed rotating frame is "**IAU_MARS**".

Other frames used within SPICE system.

Other types of frames for spacecraft, instrument platforms and instruments can be defined using the SPICE system "frames" mechanism.

Universal and Ephemeris times

Routines

LDPOOL	loads LSK file FNAME containing values of constants and leap seconds required for UTC – ET correspondence calculation. SUBROUTINE LDPOOL(FNAME) CHARACTER*(*) FNAME
UTC2ET	given a Universal Time UTC , calculates the corresponding Ephemeris Time ET . SUBROUTINE UTC2ET(UTC, ET) CHARACTER*(*) UTC DOUBLE PRECISION ET
STR2ET	given a STRING representing a time, calculates the corresponding ephemeris time ET . SUBROUTINE STR2ET (STRING, ET) CHARACTER*(*) STRING DOUBLE PRECISION ET
ET2UTC	given an Ephemeris Time ET , calculates the corresponding Universal Coordinated Time, UTC . The FORMAT parameter defines the format of UTC (can be 'C' for calendar, 'D' for day of the year, 'J' for Julian date UTC; 'ISOC' for ISO calendar format, 'ISOD' for ISO day of year format). The PREC parameter defines number of digits after decimal point in UTC seconds. SUBROUTINE ET2UTC(ET, FORMAT, PREC, UTC) DOUBLE PRECISION ET CHARACTER*(*) FORMAT INTEGER PREC CHARACTER*(*) UTC
TIMOUT	given an Ephemeris Time ET , calculates a time string, STRING in a user specified format and system. The PICTUR parameter is a string that gives a "picture" of the time format. SUBROUTINE TIMOUT (ET, PICTUR, STRING) DOUBLE PRECISION ET CHARACTER*(*) PICTUR CHARACTER*(*) STRING

Example

This fragment of code loads an LSK file (usually it's done once at the beginning of the program), calculates ET for a given UTC, adds to ET 2 hours and converts this ET back to UTC in two ways.

```
CALL LDPOOL( "\naif\data\nai000c.tls" )  
CALL STR2ET ( '1997 Jan 17 17:44:42.271', ET )  
ET = ET + 7200  
CALL ET2UTC ( ET, 'C', 3, UTC )  
CALL TIMOUT ( ET, 'YYYY MON DD HR:MN:SC.###', STRING )
```

UTC and ET formats

Universal Time UTC is a string and can appear in one of the following formats:

ISO format, for example

1986-01-18T12:19:52.18
1995-08T18:28:12

Day of the year, for example

1993-321/12:28:28.287
1992 183// 12 18 19

Calendar date, for example

1986 JAN 9 03:12:59.22451
Tue Aug 6 11:10:57 1996
2/3/1996 17:18:12.002

Julian date, for example

jd 28272.291
2451515.2981 (JD)

Ephemeris Time ET is a number of ephemeris seconds past Julian date J2000 (JD = 2451545.0 corresponds to 12:00:00 January 1, 2000 TDB).

Spacecraft On-board Time (SCLK)

Routines

LDPOOL	loads SCLK file FNAME containing values required for SCLK string format interpretation and SCLK-to-Ephemeris Time (ET) correspondence calculation. <pre>SUBROUTINE LDPOOL(FNAME) CHARACTER*(*) FNAME</pre>
SCENC	converts character representation of SCLK CLKSTR to its double precision encoding SCLKDP for the spacecraft with integer code SC .
SCDECD	makes opposite conversion. <pre>SUBROUTINE SCENC(SC, CLKSTR, SCLKDP) SUBROUTINE SCDECD(SC, SCLKDP, CLKSTR) INTEGER SC CHARACTER*(*) CLKSTR DOUBLE PRECISION SCLKDP</pre>
SCE2C	calculates for Ephemeris Time ET the corresponding double precision continuous encoding of SCLKDP for the spacecraft with ID SC .
SCT2E	makes opposite conversion. <pre>SUBROUTINE SCE2T(SC, ET, SCLKDP) SUBROUTINE SCT2E(SC, SCLKDP, ET) INTEGER SC DOUBLE PRECISION ET DOUBLE PRECISION SCLKDP</pre>
SCE2S	calculates for Ephemeris Time ET the corresponding CLKSTR represented as a character string for the spacecraft with integer code SC .
SCS2E	makes opposite conversion. <pre>SUBROUTINE SCE2T(SC, ET, CLKSTR) SUBROUTINE SCT2E(SC, CLKSTR, ET) INTEGER SC DOUBLE PRECISION ET CHARACTER*(*) CLKSTR</pre>

Example

This fragment of code loads a SCLK file for spacecraft with ID **-23** (it's done once at the beginning of the program), calculates for a given ET the corresponding double precision encoding of SCLK and converts it to character representation.

```
.....  
CALL LDPOOL( "\naif\sc23\data\sprcft23.tsc" )  
.....  
CALL SCE2C ( -23, ET, SCLKDP )  
CALL SCDECD( -23, SCLKDP, CLKSTR )  
.....
```

SCLK formats

String representation: SCLK is represented as string of **"2/123.23.59.59.255"** type and is consisting of two parts. First part **"2/"** is partition number, second **"123.23.59.59.255"** is SCLK time in this partition (in given string dots are separating fields counting days, hours, minutes, seconds, 1/256 of seconds). Different spacecrafts have different set of fields.

"Encoded" double precision representation: SCLK time is represented by double precision number containing number of ticks that on-board timer has counted from the beginning of the mission. Tick is the shortest time increment expressible by this times (for example given above it is 1/256 of second).

Constants and matrixes of planets and satellites (PCK).

Routines

LDPOOL	loads text PCK file FNAME containing constants for Solar system bodies. SUBROUTINE LDPOOL(FNAME) CHARACTER*(*) FNAME
PCKLOF	loads binary PCK file FNAME containing orientation data for one or more Solar system bodies and returns the file handle HANDLE for this file. SUBROUTINE PCKLOF (FNAME, HANDLE) CHARACTER*(*) FNAME INTEGER HANDLE
TIPBOD	calculates matrix TIPM rotating vectors from inertial reference frame with ID IRF to body-fixed reference frame for the body with ID BODY at the given ephemeris time ET . SUBROUTINE TIPBOD(IRF, BODY, ET, TIPM) CHARACTER*(*) IRF INTEGER BODY DOUBLE PRECISION ET DOUBLE PRECISION TIPM (3,3)
BODEUL	returns Euler angles — right ascension RA , declination DEC and twist W that are used for calculation of a matrix used to rotate vectors from inertial frame “J2000” to the body-fixed frame for the body with ID BODY at ephemeris time ET . Also returns longitude of prime meridian, LAMBDA , for this body (LAMBDA=0 for all planets except Mars). SUBROUTINE BODEUL(BODY, ET, RA, DEC, W, LAMBDA) INTEGER BODY DOUBLE PRECISION ET DOUBLE PRECISION RA, DEC, W, LAMBDA
TISBOD	calculates the matrix TISM used to rotate state vectors (position and velocity) from the inertial frame with name IRF to the body-fixed reference frame for the body with ID BODY at ephemeris time ET . SUBROUTINE TISBOD(IRF, BODY, ET, TISM) CHARACTER*(*) IRF INTEGER BODY DOUBLE PRECISION ET DOUBLE PRECISION TISM (6,6)
BODVAR	returns the vector VALUES (and its dimension DIM) containing value(s) for the physical parameter named ITEM for the body with ID BODY . As examples, to retrieve the axes of ellipsoid model of a planet ITEM is set to “ RADII ”, for planet nutation precession angles — “ NUT_PREC_ANGLES ”, etc. SUBROUTINE BODVAR(BODY, ITEM, DIM, VALUES) INTEGER BODY CHARACTER*(*) ITEM INTEGER DIM DOUBLE PRECISION VALUES (*)

Example

This fragment of code loads a text PCK file, calculates the matrix which rotates vectors from the inertial frame “B1950” to the body-fixed frame for Mars, and retrieves the lengths of the three axes defining the Mars ellipsoid.

```
CALL LDPOOL( "\naif\data\nai000c.tpc" )  
.....  
CALL TIPBOD( "B1950", 499, ET, MARSMT )  
CALL BODVAR( 499, "RADII", DIM, MARSRD )
```

Frame Transformations: Inertial, PCK-based and User-defined frames.

Routines

LDPOOL	loads text Frame kernel file FNAME containing frames definitions for a particular spacecraft, instrument or other structure of interest. <pre>SUBROUTINE LDPOOL(FNAME) CHARACTER*(*) FNAME</pre>
SXFORM	calculates the matrix TISM used to rotate state vectors (position and velocity) from one frame with name FROM to another frame with name TO at ephemeris time ET . <pre>SUBROUTINE SXFORM (FROM, TO, ET, XFORM) CHARACTER*(*) FROM CHARACTER*(*) TO DOUBLE PRECISION ET DOUBLE PRECISION XFORM (6, 6)</pre>

Inertial frame naming convention

The inertial frame naming convention is described in the *Inertial Reference Frames* section of this document.

PCK-based frame naming convention

Another category of frames supported in SPICE is the PCK-based set of frames (IAU body-fixed rotating frames). The naming convention for these frames is "**IAU_[BODY_NAME]**", where "**[BODY_NAME]**" is the name of the body. For example, to refer to the Mars body-fixed rotating frame use "**IAU_MARS**" in an SXFORM call.

User-defined frame naming convention

Yet another category of frames supported in SPICE is user-defined frames which can be CK-based or fixed offset. The SPICE system recognizes these frames only when a frames kernel file containing definitions for such frames is loaded into the Kernel Pool. These frames can be given any name except those which belong to the standard SPICE inertial set and any PCK-based frames already defined in the SPICE system. To avoid possible interference when frames for multiple spacecrafts and instruments are loaded into SPICE simultaneously, NAIF recommends including abbreviated spacecraft name and instrument name in the prefix of any user-defined frame name. For example the image frame for the MGS camera (MOC) can be called "**MGS_MOC_IMAGE**", and the base frame for the MCO PMIRR instrument can be called "**MCO_PMIRR_BASE**", and so on. Refer to a frame kernel for particular mission for a complete list of user-defined frames for that mission.

Example

This fragment of code loads an MGS Frames kernel file, generic SPICE LSK file, MGS SCLK file and MGS spacecraft and solar array orientation CK files and calculates the matrix which rotates vectors from the Mars body-fixed rotating frame "**IAU_MARS**" to the MGS magnetometer (MAG) +Y sensor frame "**MGS_MAG_+Y_SENSOR**".

```
.....  
CALL LDPOOL( "/kernels/mgs/frames/mgs.tf" )  
CALL LDPOOL( "/kernels/generic/lsk/naif0007.tls" )  
CALL LDPOOL( "/kernels/mgs/sclk/mgs.tsc" )  
CALL CKLPF ( "/kernels/mgs/ck/mgs_spice_c_kernel_1998-339.bc" )  
CALL CKLPF ( "/kernels/mgs/ck/mgs_solar_array_1998-339.bc" )  
.....  
CALL SXFORM( "IAU_MARS", "MGS_MAG_+Y_SENSOR", ET, XMAT )  
.....
```

Planet and Spacecraft positions (SPK).

Routines

SPKLEF	loads an SPK file FNAME containing trajectory data for one or more ephemeris bodies (planet, satellite, spacecraft, etc.) for some interval of time, and returns the file handle HANDLE for this file. SUBROUTINE SPKLEF(FNAME, HANDLE) CHARACTER*(*) FNAME INTEGER HANDLE
SPKEZ	calculates the state vector (position and velocity) STATE of one body (“target”) with respect to another body (“observer”) at ephemeris time ET . Both bodies are specified by their integer IDs, accordingly TARG for “target” and OBS for “observer”. The state vector is calculated in the requested reference frame with name FRAME from the list of frames supported within SPICE system. In accordance with the correction parameter ABERR the state vector can be calculated as apparent (ABERR="LT+S" or "CN+S"), true ("LT" or "CN"), geometric ("NONE"). This routine also returns one-way light-time from “target” to “observer” LT . SUBROUTINE SPKEZ(TARG, ET, FRAME, ABERR, OBS, STATE, LT) INTEGER TARG DOUBLE PRECISION ET CHARACTER*(*) FRAME CHARACTER*(*) ABERR INTEGER OBS DOUBLE PRECISION STATE (6) DOUBLE PRECISION LT
SPKEZR	performs the same calculation as SPKEZ but “target” body and “observer” body are specified by their names TARGNM and OBSNM instead of numeric ID codes. SUBROUTINE SPKEZ(TARGNM, ET, FRAME, ABERR, OBSNM, STATE, LT) CHARACTER*(*) TARGNM DOUBLE PRECISION ET CHARACTER*(*) FRAME CHARACTER*(*) ABERR CHARACTER*(*) OBSNM DOUBLE PRECISION STATE (6) DOUBLE PRECISION LT
SPKUEF	unloads previously loaded SPK having file handle HANDLE . SUBROUTINE SPKUEF(HANDLE) INTEGER HANDLE

Example

This fragment of code loads two SPK files (the first contains ephemeris data for Solar system bodies, the second contains trajectory data for the spacecraft with ID **-23**) covering the same period of time. It also loads a PCK file to provide data for transformation from inertial to the Mars body-fixed rotating frame. Then it calculates geometric states of Sun and spacecraft with respect to Mars center in Mars body-fixed rotating frame “IAU_MARS”. The loading of SPK and PCK files is normally done only once at the beginning of the program, while the computation of state vectors is usually repeated for many instants of time.

```
.....  
CALL LDPOOL ( '\naif\data\pck00005.tpc' )  
CALL SPKLEF ( '\naif\data\de200.bsp', HANDLE(1) )  
CALL SPKLEF ( '\naif\sc23\data\orbit142.bsp', HANDLE(2) )  
.....  
CALL SPKEZR ( 'SUN', ET, 'IAU_MARS', 'NONE', 'MARS', SUNST, SUNLT )  
CALL SPKEZ ( -23, ET, 'IAU_MARS', 'NONE', 499, SC23ST, SC23LT )
```

Attitude of spacecrafts and instrument platforms (CK).

Routines

CKLPF	loads a CK file FNAME containing attitude data for one or more spacecrafts or instruments platforms and returns the integer file handle HANDLE for this file. SUBROUTINE CKLPF(FNAME, HANDLE) CHARACTER*(*) FNAME INTEGER HANDLE
CKGP	calculates the transformation matrix CMAT used to rotate a vector from the reference frame named REF from the list of frames supported within SPICE system to the platform-fixed reference frame for the instrument platform with ID INSTR at the time SCLK that is double precision encoding of SCLK. If pointing data in the loaded file is continuous, then the matrix will be returned at exactly the requested SCLK and SCLKOUT will be equal to SCLK . If pointing data in the loaded file is discrete then the matrix will be calculated for time that is closest to the requested SCLK and belongs in the interval \pm TOL from it. This time will be returned in SCLKOUT . The flag FND will be .TRUE. if it was possible to calculate CMAT , otherwise it will be .FALSE. SUBROUTINE CKGP(INSTR, SCLK, TOL, REF, CMAT, SCLKOUT, FND) INTEGER INSTR DOUBLE PRECISION SCLK DOUBLE PRECISION TOL CHARACTER*(*) REF DOUBLE PRECISION CMAT (3,3) DOUBLE PRECISION SCLKOUT BOOLEAN FND
CKGPAV	calculates the transformation matrix CMAT and the angular velocity AV of rotation of the platform-fixed reference frame with respect to the specified reference frame named REF for instrument platform with ID INS at the time SCLK that is double precision encoding of SCLK. If pointing data in the loaded file is continuous, then the matrix and the angular velocity will be returned at exactly the requested SCLK and SOUT will be equal to SCLK . If pointing data in the loaded file is discrete then the matrix and the angular velocity will be calculated for time that is closest to the requested SCLK and belongs in the interval \pm TOL from it. This time will be returned in SCLKOUT . The flag FND will be .TRUE. if it was possible to calculate CMAT and AV , otherwise it will be .FALSE. SUBROUTINE CKGPAV(INS, SCLK, TOL, REF, CMAT, AV, SOUT, FND) INTEGER INS DOUBLE PRECISION SCLK DOUBLE PRECISION TOL CHARACTER*(*) REF DOUBLE PRECISION CMAT (3,3) DOUBLE PRECISION AV (3) DOUBLE PRECISION SOUT BOOLEAN FND
CKUPF	unloads the previously loaded CK having file handle HANDLE . SUBROUTINE CKUPF(HANDLE) INTEGER HANDLE

Example

This fragment of code loads a CK file containing pointing data for the instrument platform with ID - 23001, calculates a transformation matrix used to rotate vectors from the inertial frame "B1950" to the platform-fixed reference frame and performs this rotation on the vector **X**.

```
.....  
CALL CKLPF( "\naif\sc23\data\orbit142.bc", HANDLE )  
.....  
CALL CKGP ( -23001, SCLK, 200, "B1950", CMAT, SCLKOUT, FND )  
CALL MXV ( CMAT, X, XOUT )
```

Scientific Instruments Parameters (IK).

Routines

LDPOOL	loads an IK file named FNAME containing mounting alignment and other parameters for a particular scientific instrument. <pre>SUBROUTINE LDPOOL(FNAME) CHARACTER*(*) FNAME</pre>
RTPOOL	reads values for the instrument parameter with name NAME , stores these values in the array VALUES and returns the number of them in DIM . Flag FOUND becomes .TRUE. if the requested parameter (and its values) was found among the loaded parameters. <pre>SUBROUTINE RTPOOL(NAME, DIM, VALUES, FOUND) CHARACTER*(*) NAME INTEGER DIM DOUBLE PRECISION VALUES BOOLEAN FOUND</pre>

Example

This fragment of code loads an IK file containing parameters for the instrument with code **-23036**, the reads from the loaded data the values of Euler angles **ANG** and the corresponding rotation axes **AXS** defining mounting alignment of the instrument (attitude of instrument reference frame) relative to the instrument platform, and finally calculates the transformation matrix **MAT** that rotates vectors from the platform-fixed reference frame to the instrument-fixed reference.

```
.....  
CALL LDPOOL( "\naif\sc23\data\ins23036.ti" )  
.....  
CALL RTPOOL( "INS-23036_EULER_ANGLES", N, ANG, FOUND )  
CALL RTPOOL( "INS-23036_EULER_AXES", N, AXS, FOUND )  
CALL EUL2M ( ANG(3), ANG(2), ANG(1),  
            AXS(3), AXS(2), AXS(1), MAT )
```

Instrument parameters naming convention

The names of instrument parameters are defined in accordance with the following scheme:

INS-*nnnnn*_*item name*,

where **INS** shows that this parameter belongs to a scientific instrument, **-*nnnnn*** is the SPICE ID of this instrument and **<*item name*>** is the name of the specific parameter.

Each instrument has its own set of parameters contained in an IK file. This set and the names of the parameters are defined by the file creator. The minimum set of instrument parameters in a SPICE IK file consists of three items:

INS-*nnnnn*_EULER_ANGLES,
INS-*nnnnn*_EULER_AXES and
INS-*nnnnn*_PLATFORM_ID,

containing Euler angles and corresponding axes of rotation that specify the mounting alignment of the instrument relative to its platform and the ID of this platform.

Star Catalog

Routines

- STCL01** loads a SPICE type 1 star catalog file named **CATFNM** and returns the catalog table name **TABNAM** and the integer file handle **HANDLE** for this file.
- ```
SUBROUTINE STCL01 (CATFNM, TABNAM, HANDLE)
CHARACTER*(*) CATFNM
CHARACTER*(*) TABNAM
INTEGER HANDLE
```
- STCF01** searches through a type 1 star catalog data table named **CATNAM** and returns the number of stars **NSTARS** within a rectangle specified by West and East right ascensions, **WESTRA** and **EASTRA**, and South and North declinations, **STHDEC** and **NTHDEC**, given in radians in the J2000 inertial frame.
- ```
SUBROUTINE STCF01 (CATNAM, WESTRA, EASTRA, STHDEC, NTHDEC, NSTARS)
CHARACTER*(*)    CATNAM
DOUBLE PRECISION WESTRA
DOUBLE PRECISION EASTRA
DOUBLE PRECISION STHDEC
DOUBLE PRECISION NTHDEC
INTEGER          NSTARS
```
- STCG01** gets right ascensions **RA**, declination **DEC**, the uncertainties in right ascension, **RASIG**, and declination, **DECSIG**, catalog number **CATNUM**, spectral type **SPTYPE** and visual magnitude **VM** for a single star specified by its index **INDEX** in the list of stars that satisfy the selection criteria specified in the last call to STCF01 from a SPICE type 1 star catalog. The **RA**, **DEC**, **RASIG** and **DECSIG** are returned in the J2000 inertial frame at the catalog epoch and are given in radians.
- ```
SUBROUTINE STCG01 (INDEX, RA, DEC, RASIG, DECSIG, CATNUM, SPTYPE, VM)
INTEGER INDEX
DOUBLE PRECISION RA
DOUBLE PRECISION DEC
DOUBLE PRECISION RASIG
DOUBLE PRECISION DECSIG
INTEGER CATNUM
CHARACTER*(*) SPTYPE
DOUBLE PRECISION VMAG
```

## Example

---

This fragment of code loads a SPICE type 1 star catalog file, searches the loaded catalog for stars within a specified RA—DEC rectangle and retrieves a complete set of data for each star.

```
.....
CALL STCL01 (CATFN, TABNAM, HANDLE)
.....
CALL STCF01 (TABNAM, RAMIN, RAMAX, DECMIN, DECMAX, NSTARS)
DO I = 1, NSTARS
 CALL STCG01 (I, R(I), D(I), RS(I), DS(I), CN(I), SP(I), VM(I))
END DO
```

# Spacecraft Event Information (Data Base Kernel)

## Routines

---

**EKLEF** loads an EK file named **FNAME**, making it accessible to the EK readers and returns the integer file handle **HANDLE** for this file.

```
SUBROUTINE EKLEF (FNAME, HANDLE)
CHARACTER*(*) FNAME
INTEGER HANDLE
```

**EKFIND** finds E-kernel data that satisfy a set of constraints specified in a query string **QUERY** and returns the number of found EK data records (rows) **NMROWS**. The flag **ERROR** will be **.FALSE.** if a specified query string didn't contain any errors, otherwise it will be **.TRUE.** The error diagnostics string **ERRMSG** will contain a description of an error if such was detected (**ERROR=.TRUE.**) or it will be set blank if no errors were found in the query string .

```
SUBROUTINE EKFIND (QUERY, NMROWS, ERROR, ERRMSG)
CHARACTER*(*) QUERY
INTEGER NMROWS
LOGICAL ERROR
CHARACTER*(*) ERRMSG
```

**EKGD**  
**EKGC**  
**EKGI**

returns a double precision element **DDATA** (subroutine **EKGD**), character element **CDATA** (subroutine **EKGC**) or integer element **IDATA** (subroutine **EKGI**) from a data record (row) specified by its index **ROW** in the list of data records that satisfy the selection criteria submitted in the last call to **EKFIND**. The column to fetch data from is specified by its index **SELIDX** in the **SELECT** clause of a query string that was used with **EKFIND** to define that selection criteria, and the index of the element within the column entry is specified by **ELMENT** (**ELMENT** is always 1 for scalar columns and can be from 1 to the size of the column's entry for vector columns). The flag **NULL** will be **.TRUE.** if the specified data entry is null, otherwise it will be **.FALSE.** The flag **FOUND** will be **.TRUE.** if the specified element was found, otherwise it will be **.FALSE.**

```
SUBROUTINE EKGD (SELIDX, ROW, ELMENT, DDATA, NULL, FOUND)
SUBROUTINE EKGC (SELIDX, ROW, ELMENT, CDATA, NULL, FOUND)
SUBROUTINE EKGI (SELIDX, ROW, ELMENT, IDATA, NULL, FOUND)
INTEGER SELIDX
INTEGER ROW
INTEGER ELMENT
DOUBLE PRECISION DDATA
CHARACTER*(*) CDATA
INTEGER IDATA
LOGICAL NULL
LOGICAL FOUND
```

## *EKFIND Query Syntax (Single Table Only)*

---

The query consists of four clauses, the third and fourth of which are optional. The general form of a query involving a single table is

```
SELECT <column name> [, <column name> ...]
FROM <table name>
[WHERE <constraint expression> [AND/OR <constraint expression> ...]]
[ORDER BY <column name> [<order>] [, <column name> [<order>] ...]]
```

where brackets indicate optional items. The general form of the constraint expression is

**<column name> <operator> <RHS symbol>**

where **<RHS symbol>** is a column name or a literal value and **<operator>** is any of **EQ, GE, GT, LE, LIKE, LT, NE, NOT LIKE, <, <=, =, >, >=, !=** and **<>**. Operators **BETWEEN** and **NOT BETWEEN** are also supported.

# Spacecraft Event Information Search Example

## Example

---

This fragment of code loads an EK file containing a table called **EVENTS** containing time-type column **EVENT\_TIME**, integer column **EVENT\_ID**, double precision column **DURATION** and character column **DESC**. The data entries in the first three columns have scalar values, the data entries in the fourth column — **DESC** — are variable size arrays of up to 80 character long strings. The code then searches for events within a specified time interval and fetches data from all records that were found.

```
CALL EKLEF(FNAME, HANDLE)
.....
CALL PROMPT('Enter start UTC time> ', BEGUTC)
CALL PROMPT('Enter end UTC time> ', ENDUTC)
QUERY = 'SELECT EVENT_TIME, EVENT_ID, DURATION, DESC ' //
 'FROM EVENTS ' //
 'WHERE TIME BETWEEN ' // BEGUTC // ' AND ' // ENDUTC //
 'ORDER BY TIME'
CALL EKFIND (QUERY, NMROWS, ERROR, ERRMSG)

IF (.NOT. ERROR) THEN
 IF (NMROWS .GT. 0) THEN
 DO ROW = 1, NMROWS

 CALL EKGD (1, ROW, 1, ET, NULL, FOUND)
 IF (.NOT. NULL) THEN
 CALL ET2UTC(ET, 'C', 2, UTC(ROW))
 ELSE
 UTC(ROW) = ' '
 END IF

 CALL EKGI (2, ROW, 1, EVNTID(ROW), NULL, FOUND)
 IF (NULL) THEN
 EVNTID(ROW) = 0
 END IF

 CALL EKGD (3, ROW, 1, DURATN(ROW), NULL, FOUND)
 IF (NULL) THEN
 DURATN(ROW) = 0.D0
 END IF

 N = 1
 CALL EKGC (4, ROW, N, DESCRP(ROW,N), NULL, FOUND)
 IF (.NOT. NULL .AND. FOUND) THEN
 DO WHILE (FOUND)
 N = N + 1
 CALL EKGC (4, ROW, N, DESCRP(ROW,N), NULL, FOUND)
 END DO
 ELSE
 DESCRP(ROW,1) = ' '
 END IF

 END DO
 ELSE
 WRITE(*,*) 'No records satisfying query (' // QUERY //
 ') were found.'
 END IF
ELSE
 WRITE(*,*) 'Bad query string: ' // ERRMSG
END IF
```

# Physical and Mathematical constants

## *SPICE function declarations*

---

Any of the functions above as well as any other SPICELIB function must be implicitly declared in the declaration section of the program before it can be called in the programs code. This assures that this function will return a value of the correct when it will be used in the program statements. Two lines below declare the fuctions **SPD** and **DPR**.

```
.....
DOUBLE PRECISION DPR
DOUBLE PRECISION SPD
```

## *Example*

---

This fragment of code declares and calls **DPR** function to calculate **ANG** in degrees.

```
DOUBLE PRECISION DPR
.....
ANG = ACOS(X) * DPR ()
```

# Rectangular Coordinates.

## Routines

# Latitudinal and Geodetic coordinates.

## Routines

---

**LATCYL** calculates cylindrical coordinates — distance **RADIUS**, angle **LONGC** and height **Z**, of a point given by its latitudinal coordinates — longitude **LONG**, latitude **LAT** and distance to center **R**.

```
SUBROUTINE LATCYL (R, LONG, LAT, RADIUS, LONGC, Z)
DOUBLE PRECISION R
DOUBLE PRECISION LONG
DOUBLE PRECISION LAT
DOUBLE PRECISION RADIUS
DOUBLE PRECISION LONGC
DOUBLE PRECISION Z
```

**LATREC** calculates rectangular coordinates **RECTAN** of a point given by its latitudinal coordinates.

```
SUBROUTINE LATREC (R, LONG, LAT, RECTAN)
DOUBLE PRECISION R
DOUBLE PRECISION LONG
DOUBLE PRECISION LAT
DOUBLE PRECISION RECTAN (3)
```

**LATSPH** calculates spherical coordinates of a point given by its latitudinal coordinates.

```
SUBROUTINE LATSPH (R, LONG, LAT, RADIUS, COLAT, LONG)
DOUBLE PRECISION R
DOUBLE PRECISION LONG
DOUBLE PRECISION LAT
DOUBLE PRECISION RADIUS
DOUBLE PRECISION COLAT
DOUBLE PRECISION LONG
```

**GEOREC** calculates rectangular coordinates **RECTAN** of a point given by its geodetic coordinates — longitude **LONG**, latitude **LAT** and distance from center **ALT**. Also returns the equatorial radius of the planet ellipsoid **RE** and the flattening coefficient **F** ( $F=(R_{\text{equ}}-R_{\text{pol}})/R_{\text{equ}}$ ) of this ellipsoid.

```
SUBROUTINE GEOREC (LONG, LAT, ALT, RE, F, RECTAN)
DOUBLE PRECISION LONG
DOUBLE PRECISION LAT
DOUBLE PRECISION ALT
DOUBLE PRECISION RE
DOUBLE PRECISION F
DOUBLE PRECISION RECTAN (3)
```

**SRFREC** calculates rectangular coordinates **RECTAN** of a point on the surface of a body (planet or satellite) with ID **BODY** given by the point's planetocentric longitude **LONG** and latitude **LAT**. A PCK file containing constants for this body must be loaded before this subroutine is called.

```
SUBROUTINE SRFREC (BODY, LONG, LAT, RECTAN)
INTEGER BODY
DOUBLE PRECISION LONG
DOUBLE PRECISION LAT
DOUBLE PRECISION RECTAN (3)
```

## Example

---

This fragment of code loads PCK file and calculates rectangular coordinates of a point having geodetic longitude **LONG** and latitude **LAT** on the Mars surface.

```
.....
CALL LDPOOL("\naif\data\naiif000c.tpc")
.....
CALL SRFREC(499, LONG, LAT, VECT)
```

## Simple operations on vectors.

### *Routines*

---

|               |                                                                                                                                                                                    |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VADD</b>   | adds two vectors <b>V1</b> and <b>V2</b> and writes result in vector <b>VOUT</b> .<br><b>SUBROUTINE VADD ( V1, V2, VOUT )</b>                                                      |
| <b>VSUB</b>   | subtracts vector <b>V2</b> from vector <b>V1</b> and writes result vector in <b>VOUT</b> .<br><b>SUBROUTINE VSUB ( V1, V2, VOUT )</b>                                              |
| <b>VCRSS</b>  | computes cross product of vectors <b>V1</b> and <b>V2</b> and writes result vector in <b>VOUT</b> .<br><b>SUBROUTINE VCRSS ( V1, V2, VOUT )</b>                                    |
| <b>VDOT</b>   | returns dot product of two vectors <b>V1</b> and <b>V2</b> .<br><b>DOUBLE PRECISION FUNCTION VDOT ( V1, V2 )</b>                                                                   |
| <b>VSCL</b>   | multiplies vector <b>V1</b> and scalar <b>S</b> and writes result in vector <b>VOUT</b> .<br><b>SUBROUTINE VSCL ( S, V1, VOUT )</b>                                                |
| <b>VMINUS</b> | negates vector <b>V1</b> and writes result in vector <b>VOUT</b> .<br><b>SUBROUTINE VMINUS ( V1, VOUT )</b>                                                                        |
| <b>VEQU</b>   | makes vector <b>VOUT</b> equal to vector <b>V1</b> .<br><b>SUBROUTINE VEQU ( V1, VOUT )</b>                                                                                        |
| <b>VZERO</b>  | indicates whether vector <b>V1</b> is the zero vector. If “yes”, returns <b>.TRUE.</b> .<br><b>LOGICAL FUNCTION VZERO ( V1 )</b>                                                   |
| <b>VSEP</b>   | computes the separation angle between two vectors <b>V1</b> and <b>V2</b> . Returns zero if one of vectors is the zero vector.<br><b>DOUBLE PRECISION FUNCTION VSEP ( V1, V2 )</b> |
| <b>VDIST</b>  | returns distance between two vectors <b>V1</b> and <b>V2</b> , equal to $^{\circ}\mathbf{V1-V2}^{\circ}$ .<br><b>DOUBLE PRECISION FUNCTION VDIST ( V1, V2 )</b>                    |
| <b>VNORM</b>  | computes magnitude of vector <b>V1</b> .<br><b>DOUBLE PRECISION FUNCTION VNORM ( V1 )</b>                                                                                          |
| <b>VHAT</b>   | finds the unit vector <b>VOUT</b> along with vector <b>V1</b> .<br><b>SUBROUTINE VHAT ( V1, VOUT )</b>                                                                             |
| <b>UCRSS</b>  | finds unit vector <b>VOUT</b> along with cross product of vectors <b>V1</b> and <b>V2</b> .<br><b>SUBROUTINE UCRSS ( V1, V2, VOUT )</b>                                            |
| <b>UNORM</b>  | finds magnitude <b>VMAG</b> of and unit vector <b>VOUT</b> along with vector <b>V1</b> .<br><b>SUBROUTINE UNORM ( V1, VOUT, VMAG )</b>                                             |

### *Arguments of subroutines*

---

Input and output parameters of the routines listed above should be declared as follows:

```
DOUBLE PRECISION V1 (3)
DOUBLE PRECISION V2 (3)
DOUBLE PRECISION VOUT (3)
DOUBLE PRECISION S
DOUBLE PRECISION VMAG
```

# Projections, linear combinations and rotations of vectors.

## Routines

---

|               |                                                                                                                                                                                                                                                                                                                                                              |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>VPERP</b>  | finds the component of vector <b>V1</b> that is rectangular to vector <b>V2</b> and writes it into vector <b>VOUT</b> .<br><b>SUBROUTINE VPERP ( V1, V2, VOUT )</b>                                                                                                                                                                                          |
| <b>VPROJ</b>  | finds the projection of vector <b>V1</b> onto vector <b>V2</b> and writes it in vector <b>VOUT</b> .<br><b>SUBROUTINE VPROJ ( V1, V2, VOUT )</b>                                                                                                                                                                                                             |
| <b>VROTV</b>  | rotates vector <b>V1</b> about axis vector <b>V2</b> by angle <b>ANGLE</b> and writes result vector in <b>VOUT</b> .<br><b>SUBROUTINE VROTV ( V1, V2, ANGLE, VOUT )</b>                                                                                                                                                                                      |
| <b>ROTVEC</b> | rotates vector <b>V1</b> about axis <b>IAXIS</b> given by its ID (for “X” axis ID is 1, “Y”—2, “Z”—3) by angle <b>ANGLE</b> and writes the result in vector <b>VOUT</b> .<br><b>SUBROUTINE ROTVEC ( V1, ANGLE, IAXIS, VOUT )</b>                                                                                                                             |
| <b>NPLNPT</b> | finds point <b>VOUT</b> nearest from point <b>V3</b> and belonging the line given by point <b>V1</b> and direction <b>V2</b> and calculates distance <b>DIST</b> between points <b>V3</b> and <b>VOUT</b> .<br><b>SUBROUTINE NPLNPT ( V1, V2, V3, VOUT, DIST )</b>                                                                                           |
| <b>VPRJP</b>  | finds projection of vector <b>V1</b> into plane <b>PLANE</b> and writes result vector in <b>VOUT</b> .<br><b>SUBROUTINE VPRJP ( V1, PLANE, VOUT )</b>                                                                                                                                                                                                        |
| <b>VPRJPI</b> | finds the vector <b>VOUT</b> in specified plane <b>PROJPL</b> that maps to vector <b>V1</b> in another plane <b>INVPL</b> under orthogonal projection. The flag <b>FOUND</b> becomes <b>.FALSE.</b> if the required vector couldn't be computed (planes are orthogonal or almost orthogonal).<br><b>SUBROUTINE VPRJPI ( V1, PROJPL, INVPL, VOUT, FOUND )</b> |
| <b>VLCOM</b>  | calculates linear combination of two vectors <b>V1</b> multiplied by <b>A</b> and <b>V2</b> multiplied by <b>B</b> and writes result in vector <b>VOUT</b> .<br><b>SUBROUTINE VLCOM ( A, V1, B, V2, VOUT )</b>                                                                                                                                               |
| <b>VLCOM3</b> | calculates linear combination of three vectors <b>V1</b> , <b>V2</b> and <b>V3</b> multiplied accordingly by <b>A</b> , <b>B</b> and <b>C</b> and returns it in vector <b>VOUT</b> .<br><b>SUBROUTINE VLCOM3 ( A, V1, B, V2, C, V3, VOUT )</b>                                                                                                               |

## Routines arguments

---

Input and output parameters of the routines listed above should be declared as shown below. The **UBPL** parameter is used for **PLANE** type variable declarations.

```
DOUBLE PRECISION V1 (3)
DOUBLE PRECISION V2 (3)
DOUBLE PRECISION V3 (3)
DOUBLE PRECISION VOUT (3)
DOUBLE PRECISION ANGLE
DOUBLE PRECISION DIST
DOUBLE PRECISION A
DOUBLE PRECISION B
DOUBLE PRECISION C
LOGICAL FOUND
INTEGER IAXIS

INTEGER UBPL
PARAMETER (UBPL = 4)
DOUBLE PRECISION PLANE (UBPL)
DOUBLE PRECISION PROJPL(UBPL)
DOUBLE PRECISION INVPL (UBPL)
```

## Operations on matrixes.

---

|              |                                                                                                                                                                   |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MXM</b>   | multiplies matrix <b>M1</b> and matrix <b>M2</b> and writes result in matrix <b>MOUT</b> .<br><b>SUBROUTINE MXM ( M1, M2, MOUT )</b>                              |
| <b>MXMT</b>  | multiplies matrix <b>M1</b> and the transpose of matrix <b>M2</b> and writes result in matrix <b>MOUT</b> .<br><b>SUBROUTINE MXMT ( M1, M2, MOUT )</b>            |
| <b>MXV</b>   | multiplies matrix <b>M1</b> and vector <b>V1</b> and writes result in vector <b>VOUT</b> .<br><b>SUBROUTINE MXV ( M1, V1, VOUT )</b>                              |
| <b>MTXM</b>  | multiplies the transpose of matrix <b>M1</b> and matrix <b>M2</b> and writes result in matrix <b>MOUT</b> .<br><b>SUBROUTINE MTXM ( M1, M2, MOUT )</b>            |
| <b>MTXV</b>  | multiplies the transpose of matrix <b>M1</b> and vector <b>V1</b> and writes result in vector <b>VOUT</b> .<br><b>SUBROUTINE MTXV ( M1, V1, VOUT )</b>            |
| <b>VTMV</b>  | returns the multiplication of the transpose of vector <b>V1</b> , matrix <b>M1</b> and vector <b>V2</b> .<br><b>DOUBLE PRECISION FUNCTION VTMV ( V1, M1, V2 )</b> |
| <b>XPOSE</b> | finds the transpose of matrix <b>M1</b> and writes it in matrix <b>MOUT</b> .<br><b>SUBROUTINE XPOSE ( M1, MOUT )</b>                                             |
| <b>MEQU</b>  | sets matrix <b>MOUT</b> equal to matrix <b>M1</b> .<br><b>SUBROUTINE MEQU ( M1, MOUT )</b>                                                                        |
| <b>DET</b>   | returns the determinant of matrix <b>M1</b> .<br><b>DOUBLE PRECISION FUNCTION DET ( M1 )</b>                                                                      |
| <b>TRACE</b> | returns the trace of matrix <b>M1</b> .<br><b>DOUBLE PRECISION FUNCTION TRACE ( M1 )</b>                                                                          |

### *Routines arguments*

---

Input and output parameters of the routines listed above should be declared as follows:

```
DOUBLE PRECISION V1 (3)
DOUBLE PRECISION V2 (3)
DOUBLE PRECISION VOUT (3)
DOUBLE PRECISION M1 (3,3)
DOUBLE PRECISION M2 (3,3)
DOUBLE PRECISION MOUT (3,3)
```

### *Example*

---

This fragment of code calculates the transformation matrix **MJ2INS** which rotates vectors from the inertial frame “J2000” to the instrument reference frame using two intermediate transformation matrixes: from “J2000” to instrument platform **MJ2PL**, and from platform to instrument **MPL2IN**. It then finds the position of the Sun **SUNINS** in the instrument reference frame.

```
.....
CALL MXM (MPL2IN, MJ2PL, MJ2INS)
CALL MXV (MJ2INS, SUNJ, SUNINS)
```

## Operations on planes.

### *PLANE data type*

---

An array of dimension 4 is used in the SPICE system for representation of planes. It is recommended for **PLANE** type variable declaration to use parameter **UBPL** for dimension declarations.

```
INTEGER UBPL
PARAMETER (UBPL = 4)
DOUBLE PRECISION PLANE (UBPL)
```

### *Routines*

|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NVC2PL</b> | creates a plane <b>PLANE</b> using a normal vector <b>NORMAL</b> and the distance from origin to plane <b>CONST</b> .<br><b>SUBROUTINE NVC2PL ( NORMAL, CONST, PLANE )</b>                                                                                                                                                             |
| <b>NVP2PL</b> | creates a plane <b>PLANE</b> using a normal vector <b>NORMAL</b> and a point <b>POINT</b> belonging to plane.<br><b>SUBROUTINE NVP2PL ( NORMAL, POINT, PLANE )</b>                                                                                                                                                                     |
| <b>PSV2PL</b> | creates a plane <b>PLANE</b> using a point in plane <b>POINT</b> and two linear independent vectors <b>V1</b> and <b>V2</b> .<br><b>SUBROUTINE PSV2PL ( POINT, V1, V2, PLANE )</b>                                                                                                                                                     |
| <b>PL2NVC</b> | calculates for plane <b>PLANE</b> its normal vector <b>NORMAL</b> and distance from plane to origin <b>CONST</b> .<br><b>SUBROUTINE PL2NVC ( PLANE, NORMAL, CONST )</b>                                                                                                                                                                |
| <b>PL2NVP</b> | calculates for plane <b>PLANE</b> its normal vector <b>NORMAL</b> and point <b>POINT</b> belonging to it and nearest to the origin.<br><b>SUBROUTINE PL2NVP ( PLANE, NORMAL, POINT )</b>                                                                                                                                               |
| <b>PL2PSV</b> | calculates for plane <b>PLANE</b> the point <b>POINT</b> nearest to the origin and two orthogonal vectors <b>V1</b> and <b>V2</b> lying in it.<br><b>SUBROUTINE PL2PSV ( PLANE, POINT, V1, V2 )</b>                                                                                                                                    |
| <b>INRYPL</b> | finds the intersection of a ray given by starting point <b>VERTEX</b> , direction <b>DIR</b> and plane <b>PLANE</b> , and returns the number of intersection point in <b>NXPTS</b> (can be 0 or 1) and the coordinates of the point in <b>XPT</b> (if <b>NXPTS=1</b> ).<br><b>SUBROUTINE INRYPL ( VERTEX, DIR, PLANE, NXPTS, XPT )</b> |

### *Routines arguments*

---

Input and output parameters of the routines listed above should be declared as shown below:

```
INTEGER UBPL
PARAMETER (UBPL = 4)
DOUBLE PRECISION PLANE (UBPL)

DOUBLE PRECISION NORMAL (3)
DOUBLE PRECISION CONST
DOUBLE PRECISION POINT (3)
DOUBLE PRECISION V1 (3)
DOUBLE PRECISION V2 (3)
DOUBLE PRECISION VERTEX (3)
DOUBLE PRECISION DIR (3)
INTEGER NXPTS
DOUBLE PRECISION XPT (3)
```

## Operations on ellipses.

### *ELLIPSE data type*

---

A double precision array of dimension 9 is used in the SPICE system for representation of ellipses in 3-dimensional space. It is recommended for **ELLIPSE** type variable declaration to use the **UBEL** parameter for dimension declarations.

```
INTEGER UBEL
PARAMETER (UBEL = 9)
DOUBLE PRECISION ELLIPS (UBEL)
```

### *Routines*

---

|               |                                                                                                                                                                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CGV2EL</b> | creates an ellipse <b>ELLIPS</b> using its center <b>CENTER</b> and two generating vectors <b>V1</b> and <b>V2</b> (vectors can be non-orthogonal and even linearly dependent: in the last case the ellipse will be degenerate).<br><br>SUBROUTINE CGV2EL ( CENTER, V1, V2, ELLIPS ) |
| <b>EL2CGV</b> | finds for ellipse <b>ELLIPS</b> its center <b>CENTER</b> and vectors <b>SMAJOR</b> and <b>SMINOR</b> representing its axes.<br><br>SUBROUTINE EL2CGV ( ELLIPS, CENTER, SMAJOR, SMINOR )                                                                                              |
| <b>SAELGV</b> | given two generating vectors, <b>V1</b> and <b>V2</b> , finds ellipse's axes vectors <b>SMAJOR</b> and <b>SMINOR</b> .<br><br>SUBROUTINE SAELGV ( V1, V2, SMAJOR, SMINOR )                                                                                                           |
| <b>INELPL</b> | finds intersection of ellipse <b>ELLIPS</b> and plane <b>PLANE</b> and writes number of intersection points to <b>NXPTS</b> and coordinates of these points in <b>XPT1</b> and <b>XPT2</b> .<br><br>SUBROUTINE INELPL ( ELLIPS, PLANE, NXPTS, XPT1, XPT2 )                           |
| <b>NPELPT</b> | finds on ellipse <b>ELLIPS</b> the point <b>NRPT</b> nearest to a given point <b>POINT</b> and the distance between these points <b>DIST</b> .<br><br>SUBROUTINE NPELPT ( POINT, ELLIPS, NRPT, DIST )                                                                                |
| <b>PJELPL</b> | finds projection of ellipse <b>ELLIPS</b> on the plane <b>PLANE</b> and write it in ellipse <b>ELLOUT</b> .<br><br>SUBROUTINE PJELPL ( ELLIPS, PLANE, ELLOUT )                                                                                                                       |

### *Routines arguments*

---

Input and output parameters of the routines listed above should be declared as shown below:

```
INTEGER UBEL
PARAMETER (UBEL = 9)
DOUBLE PRECISION ELLIPS (UBEL)
DOUBLE PRECISION ELLOUT (UBEL)
```

```
INTEGER UBPL
PARAMETER (UBPL = 4)
DOUBLE PRECISION PLANE (UBPL)
```

```
DOUBLE PRECISION V1 (3)
DOUBLE PRECISION V2 (3)
DOUBLE PRECISION SMAJOR (3)
DOUBLE PRECISION SMINOR (3)
INTEGER NXPTS
DOUBLE PRECISION XPT1 (3)
DOUBLE PRECISION XPT2 (3)
DOUBLE PRECISION NRPT (3)
DOUBLE PRECISION DIST
```

## Operations on ellipsoids.

### *Routines*

---

|               |                                                                                                                                                                                                                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NEARPT</b> | finds on an ellipsoid given by its axes <b>A</b> , <b>B</b> and <b>C</b> , the point <b>NRPT</b> nearest to a given point <b>POINT</b> , and returns the distance between them in <b>DIST</b> .<br><br>SUBROUTINE NEARPT ( POINT, A, B, C, NRPT, DIST )                                                                                                   |
| <b>SURFPT</b> | finds intersection of a ray given by its starting point <b>VERTEX</b> and direction <b>DIR</b> and an ellipsoid given by its axes <b>A</b> , <b>B</b> and <b>C</b> , and writes coordinates of this point in <b>XPT</b> . The flag <b>FOUND</b> becomes <b>.TRUE.</b> if such point exists.<br><br>SUBROUTINE SURFPT ( VERTEX, DIR, A, B, C, XPT, FOUND ) |
| <b>SURFNM</b> | finds the unit normal vector <b>NORMAL</b> to the surface of an ellipsoid at the point <b>POINT</b> on the ellipsoid given by axes <b>A</b> , <b>B</b> and <b>C</b> .<br><br>SUBROUTINE SURFNM ( A, B, C, POINT, NORMAL )                                                                                                                                 |
| <b>EDLIMB</b> | finds limb on an ellipsoid given by axes <b>A</b> , <b>B</b> and <b>C</b> as seen from point <b>VIEWPT</b> and returns it in <b>ELLIPSE</b> type variable <b>LIMB</b> .<br><br>SUBROUTINE EDLIMB ( A, B, C, VIEWPT, LIMB )                                                                                                                                |
| <b>NPEDLN</b> | finds on an ellipsoid given by axes <b>A</b> , <b>B</b> and <b>C</b> the point <b>NRPT</b> nearest to the line given by point <b>POINT</b> and direction <b>DIR</b> , and calculates the distance <b>DIST</b> between the line and point.<br><br>SUBROUTINE NPEDLN ( A, B, C, POINT, DIR, NRPT, DIST )                                                    |
| <b>INEDPL</b> | finds the ellipse <b>ELLIPS</b> which is the intersection of ellipsoid given by axes <b>A</b> , <b>B</b> and <b>C</b> and plane <b>PLANE</b> . The flag <b>FOUND</b> becomes <b>.TRUE.</b> if such an intersection exists.<br><br>SUBROUTINE INEDPL ( A, B, C, PLANE, ELLIPS, FOUND )                                                                     |

### *Routines arguments*

---

Input and output parameters of the routines listed above should be declared as shown below:

```
DOUBLE PRECISION A
DOUBLE PRECISION B
DOUBLE PRECISION C
DOUBLE PRECISION POINT (3)
DOUBLE PRECISION NRPT (3)
DOUBLE PRECISION VERTEX (3)
DOUBLE PRECISION DIR (3)
INTEGER NXPTS
DOUBLE PRECISION XPT (3)
DOUBLE PRECISION DIST
DOUBLE PRECISION VIEWPT (3)
LOGICAL FOUND

INTEGER UBEL
PARAMETER (UBEL = 9)
DOUBLE PRECISION LIMB (UBEL)
DOUBLE PRECISION ELLIPS (UBEL)

INTEGER UBPL
PARAMETER (UBPL = 4)
DOUBLE PRECISION PLANE (UBPL)
```

## Creation of transformation matrixes.

### Routines

---

|               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ROTATE</b> | calculates the matrix <b>MOUT</b> which rotates vectors about axis <b>IAXIS</b> (for “X” axis ID is 1, “Y”—2, “Z”—3) by angle <b>ANGLE</b> .<br><br>SUBROUTINE ROTATE ( ANGLE, IAXIS, MOUT )<br>DOUBLE PRECISION ANGLE<br>INTEGER IAXIS<br>DOUBLE PRECISION MOUT ( 3,3 )                                                                                                                                                                                                                                                                                                                                                               |
| <b>ROTMAT</b> | rotates matrix <b>M1</b> by angle <b>ANGLE</b> about <b>IAXIS</b> axis (“X”—1, “Y”—2, “Z”—3) and returns resulting matrix in <b>MOUT</b> . So, <b>MOUT</b> = <b>[ANGLE]</b> <b>IAXIS</b> * <b>M1</b> , where <b>[ANGLE]</b> <b>IAXIS</b> is the matrix which rotates vectors about <b>IAXIS</b> axis by angle <b>ANGLE</b> .<br><br>SUBROUTINE ROTMAT ( M1, ANGLE, IAXIS, MOUT )<br>DOUBLE PRECISION M1 ( 3,3 )<br>DOUBLE PRECISION ANGLE<br>INTEGER IAXIS<br>DOUBLE PRECISION MOUT ( 3,3 )                                                                                                                                            |
| <b>TWOVEC</b> | finds transformation matrix <b>MOUT</b> which rotates vectors to the reference frame having a given vector <b>AXDEF</b> as specified axis <b>INDEXA</b> (“X”—1, “Y”—2, “Z”—3) and having a second given vector <b>PLNDEF</b> lying in coordinate plane <b>INDEXA</b> — <b>INDEXP</b> (axis <b>INDEXP</b> is defined by the same rule). The direction of the third axis is taken from condition that this frame is right-handed.<br><br>SUBROUTINE TWOVEC ( AXDEF, INDEXA, PLNDEF, INDEXP, MOUT )<br>DOUBLE PRECISION AXDEF ( 3 )<br>INTEGER INDEXA<br>DOUBLE PRECISION PLNDEF ( 3 )<br>INTEGER INDEXP<br>DOUBLE PRECISION MOUT ( 3,3 ) |
| <b>EUL2M</b>  | calculates the transformation matrix <b>MOUT</b> from Euler angles <b>ANG1</b> , <b>ANG2</b> and <b>ANG3</b> and their corresponding axes of rotation <b>AX1</b> , <b>AX2</b> and <b>AX3</b> (“X”—1, “Y”—2, “Z”—3).<br><br>SUBROUTINE EUL2M ( ANG3, ANG2, ANG1, AX3, AX2, AX1, MOUT )<br>DOUBLE PRECISION ANG3, ANG2, ANG1<br>INTEGER AX3, AX2, AX1<br>DOUBLE PRECISION MOUT ( 3,3 )                                                                                                                                                                                                                                                   |
| <b>M2EUL</b>  | calculates Euler angles <b>ANG1</b> , <b>ANG2</b> and <b>ANG3</b> and the corresponding axes of rotation <b>AX1</b> , <b>AX2</b> and <b>AX3</b> (“X”—1, “Y”—2, “Z”—3) for the transformation matrix <b>M1</b> .<br><br>SUBROUTINE M2EUL ( M1, ANG3, ANG2, ANG1, AX3, AX2, AX1 )<br>DOUBLE PRECISION M1 ( 3,3 )<br>DOUBLE PRECISION ANG3, ANG2, ANG1<br>INTEGER AX3, AX2, AX1                                                                                                                                                                                                                                                           |

### Example

---

This fragment of code creates matrix **MROT** from given right ascension **RA**, declination **DEC** and twist **TWIST**.

```
.....
CALL EUL2M (TWIST, HALFPI()-DEC, RA, 3, 2, 3, MROT)
```

## Orbital elements.

### *Orbital elements representation*

---

Orbital elements are stored in double precision arrays containing **8** numbers.

```
DOUBLE PRECISION ELTS (8)
```

The elements of this array contain:

```
ELTS(1) distance to pericenter R_p , (km);
ELTS(2) eccentricity e ;
ELTS(3) inclination i (rad);
ELTS(4) longitude of ascending node Ω (rad);
ELTS(5) argument of periapse ω (rad);
ELTS(6) mean anomaly at epoch E (rad);
ELTS(7) epoch t (ephemeris seconds past J2000);
ELTS(8) gravitational parameter of planet μ (km3/sec2).
```

### *Routines*

---

**CONICS** calculates the position and velocity **STATE** of an orbiting body (spacecraft) from a set of elliptic, hyperbolic or parabolic orbital elements **ELTS** at a time given as ephemeris time **ET**.

```
SUBROUTINE CONICS (ELTS, ET, STATE)
DOUBLE PRECISION ELTS (8)
DOUBLE PRECISION ET
DOUBLE PRECISION STATE (6)
```

**OSCELT** given the state **STATE** of an orbiting body at ephemeris time **ET**, and given the gravitational parameter of the planet **MU**, calculates orbital elements **ELTS** for this orbiting body.

```
SUBROUTINE OSCELT (STATE, ET, MU, ELTS)
DOUBLE PRECISION STATE (6)
DOUBLE PRECISION ET
DOUBLE PRECISION MU
DOUBLE PRECISION ELTS (8)
```

### *Example*

---

This fragment of code reads position and velocity of a Mars-orbiting spacecraft with ID **-23** from loaded SPK files, transforms this state from inertial frame “J2000” to Mars “equator—north pole” non-rotating reference frame and calculates from this new state the orbital elements for the spacecraft.

```
.....
CALL SPKLEF("\naif\sc23\data\orbit036.bsp", HANDLE)
CALL SPKEZ (-23, ET, "J2000", "NONE", 499, STATE, LT)

DO I = 1, 3
 VEC(I) = STATE (I)
 VEL(I) = STATE (I+3)
END DO

CALL MXV (MJ2MRS, VEC, VEC)
CALL MXV (MJ2MRS, VEL, VEL)

DO I = 1, 3
 STATE (I) = VEC(I)
 STATE (I+3) = VEL(I)
END DO

CALL OSCELT (STATE, ET, MARSMU, ORBELM)
```
